

# Thermal runaway of lithium-ion batteries in energy storage cabinets

## Overview

---

When lithium-ion cells go into thermal runaway, their temperature rapidly increases, vaporizing the electrolyte and increasing pressure until the cell vents. This venting behavior is crucial in terms of: Amount of heat dissipated from the cell during failure. Mechanical. Within a densely packed battery energy storage system, a single cell's TR can propagate to neighboring cells through heat transfer, potentially escalating into a catastrophic module- or container-level fire event. Such incidents pose severe risks to personnel, infrastructure, and grid operations. Thermal runaway is a major challenge in the Li-ion battery field due to its uncontrollable and irreversible nature, which can lead to fires and explosions, threatening the safety of the public.
